

WatchBox

Tell Telegram what to watch.

It spawns a [dedicated Daytona sandbox](#) that watches 24/7 and an LLM on [Nosana GPUs](#) decides if it matters.

@Daytonakorea_bot

"Tell me when X happens" is still a coding task

Three things break today

Your laptop must stay on

Every watch is a script on your own machine. Close the lid, watching stops.

Alerts only match keywords

Google Alerts / IFTTT can't answer "is this *bad* news?" — meaning needs an LLM.

Watchers die silently

One cron job breaks, everything shares its fate. (My own crawler was dead 18 days before I noticed.)

One sentence → one isolated watcher

Sponsors are the skeleton, not decoration

Live today

Real phone, real sandboxes, real judgments — 15:28 KST today

What the phone shows

- ① `/watch` in Korean → Nosana parses intent → Daytona sandbox #1 born in **1.21 s** (ready 7.6 s)
- ② second watch → sandbox #2 in **0.67 s**
- ③ `/list` → two isolated boxes, per-watch cost
- ④ 🛎 real headline judged by Nosana Qwen: "Huawei overtakes Nvidia in China"

Why these sponsors, not a VPS

Remove either one and the product disappears

Daytona — a computer per watch

Born in ~2 s from one sentence, stateful while it lives, gone on `/stop`. 100 watches = 100 boxes that never touch each other. The bot itself runs there too — laptop closed.

Nosana — meaning, cheaply

"Negative news?" is a judgment, not a keyword. Running it on a Nosana GPU makes 24/7 judging affordable; without it this is Google Alerts.

DNSimple — a name for the status page

Optional. `dns.py` points `watch.<domain>` at the sandbox preview URL.

What's next — and what's honestly missing

Login sites

KTX seats, real-estate listings need cookies. Next: Daytona Secrets so even the bot never sees them.

Cost

An always-on sandbox is ~\$1.6/day. Next: auto-stop between checks, wake on schedule → ~1/50.

First user: me

Conference deadlines, price triggers, pool schedules. If a 9-27B judge isn't good enough, the Nosana axis gets cut — that's the kill condition.
